ABSTRACTS

Used frying oil (UFO) has a great potential as feedstock for biodiesel production. This study aims to develop an artificial neural network (ANN) model to predict biodiesel yield produced from base-catalyzed transesterification of UFO. The experiment was performed with 100 mL of UFO at three different molar ratios (oil:methanol) (namely 1:4, 1:5, and 1:6), conducted with reaction temperatures of 30 to 55°C (raised by 5°C), and reaction time of 0.25, 0.5, 1, 2, 3, 6, 8, and 10 minutes. Prediction model was based on ANN model consisting of three layers with 27 combinations of three activation functions (tansig, logsig, purelin). All activation function architectures were trained using Levenberg-Marquardt train type with 126 data set (87.5%) and learning rate of 0.001. Model validation used 18 data set (12.5%) measured at reaction time of 8 min. Results showed that two ANN models with activation function of logsig-purelin-logsig and purelin-logsig-tansig be the best with *RRMSE* of 2.41% and 2.44% with R^2 of 0.9355 and 0.9391, respectively. Predictions of biodiesel yield using ANN models are significantly better than those of first-order kinetics.

1. INTRODUCTION

Biodiesel is an alternative energy source for diesel fuel offering several advantages. First, biodiesel is made from vegetable oils or animal fats so it is classified as a

renewable, biodegradable, and nontoxic energy source (Khan *et al.*, 2013). Biodiesel, therefore, is ecologically friendly because the production and application of biodiesel results in lower greenhouse gas (GHG) emissions than petroleum fuels do. Studies

in the United States (Sheehan *et al.*, 1998) revealed that based on life cycle analysis biodiesel is able to decrease GHG emission 78% as compared to petroleum diesel fuel. Other works using various feedstock in different countries also reported that biodiesel application results in lower GHG such as in India with *Jatropha curcas* (Kumar *et al.*, 2012; Achten *et al.*, 2010), China with various oils (Hou *et al.*, 2011; Guo *et al.*, 2010), Southeast Asia (Indonesia, Malaysia, Thailand) with palm oil (Siregar *et al.*, 2015; Harsono *et al.*, 2012; Hassan *et al.*, 2011; Silalertruksa & Gheewala, 2012), Brazilia with soybean oil (Oliveira *et al.*, 2017), and Europe with rapeseed oil (Malça & Freire, 2011). Second, unlike fossil fuels which are bestowed to a few countries, oil-plants producing biodiesel feedstock are spread throughout the world so that geopolitically biodiesel can be one that increase energy security (Paltsev, 2016).

Utilization of vegetable oils as feedstock for biodiesel production is more expensive because the cost of raw materials can reach 80 to 85% of operational costs (Canakci & Sanli, 2008; Hindryawati *et al.*, 2014). One potential cheaper raw material is used frying oil (UFO), which is not allowed to be dumped directly because it has a high COD value. In addition, UFO contains toxic compound formed during high temperature heating like hydroperoxides and aldehydes. When these compounds ingested through consumed food, they may be responsible for increasing blood pressure (hypertension) and attributable to cardiovascular diseases and diabetes (Leong *et al.*, 2015; Jaarin *et al.*, 2018). Repeatedly heated cooking oils even produce carcinogenic compounds such as polycyclic aromatic hydrocarbons that relate to the incidence of tumor and cancer diseases (Ganesan *et al.*, 2017). Therefore, using UFO repeatedly to fry food or to make food-related ingredient, such as chili sauce, may endanger human health.

The potential of used cooking oil in Indonesia is quite large because the consumption of cooking oil tends to increase from 0.198 L/capita per week in 2007 to 0.205 in 2012 and 0.221 in 2017. This figure is very close with the study of Fujita *et al.* (2013) in Bogor, which found cooking oil consumption of one family is 3L/month or 36 L/year. With a proper management, UFO has great potential to be used as energy sources in the form of biodiesel to replace diesel oil (Chhetri *et al.*, 2008). The development of biodiesel from UFO will provide a healthier choice in the utilization of UFO.

The reaction usually chosen to produce biodiesel from oil is transesterification with methanol and a basic catalyst (Fajardo *et al.*, 2011). For every mol of triglyceride or vegetable oil, the process stoichiometrically required three mols of methanol to produce three mols biodiesel or FAME (fatty acid methyl ester) and one mol glycerol, as presented in Equation (1).

Important factors in biodiesel synthesis, among other, include molar ratio (MR) of oil to methanol, reaction temperature (T), and reaction duration (t). Transesterification is a reversible and equilibrium reaction so that to obtain maximum yield should be carried out with excess of methanol (Ejikeme *et al.*, 2010), rather than 1:3 as in Equation 1. The disadvantage of this reaction is that there may be a side reaction in the form of saponification, which will consume the catalyst so that reducing biodiesel yield, especially if the FFA content in UFO is quite high (Narasimharao *et al.*, 2007). The relation of biodiesel yield and dependent variables is unlinear and so complex that require a robust model to accurately predict the yield. Conventional approaches such as

kinetics analysis can be applied successfully in certain constrained environments, but it is not flexible in different conditions. The complexity of these relationships can be analyzed using ANN (artificial neural network) models so as to produce high accuracy prediction of biodiesel yield (Lavalle *et al.*, 2012; Seo, 2013).

ANN model has been an important tool to solve many problems in a wide range of areas such as pattern recognition, function approximation, categorization, prediction, optimization, associative memory, and control (Jain *et al.*, 1996). Recently, ANN model is explored to predict biodiesel yield (Thoai *et al.*, 2018). The ANN model has also been used to predict biodiesel properties such as viscosity, cloud point, flash point, pour point, and cetane number (Giwa *et al.*, 2015; Al-Shanableh *et al.*, 2016).

The general objective of this study was to predict biodiesel yield resulted from UFO transesterification reaction which is broke down into three specific objectives. First, it was to examine the relationship between molar ratio, reaction temperature, and reaction time as independent variables to biodiesel yield as the dependent variable. Second, it was to develop ANN models to predict biodiesel yield from UFO transesterification reaction. Third, it was to validate ANN models to obtain the most accurate models in predicting biodiesel yield.

2. MATERIALS AND METHODS

2.1. Biodiesel synthesis

The UFO was collected from fried food pedlars in the vicinity of the University of Lampung. Biodiesel was synthesized by transesterification reaction using 100 ml UFO with methanol and NaOH. Combination of three different molar ratios (*MR*) of oil to methanol (1:4; 1:5; 1:6), six temperature (*T*) levels (30, 35, 40, 45, 50, 55°C), and eight

points of reaction time, *t* (0.25, 0.5, 1, 2, 3, 6, 8, 10 minutes) was run to evaluate their effect on biodiesel yield. Detail of materials and processing method have been recently reported elsewhere (Haryanto *et al.*, 2019).

2.2. ANN model development

Figure 1 shows a step-by-step ANN model development to validation. The ANN model to be developed is back-propagation type with supervised learning method.

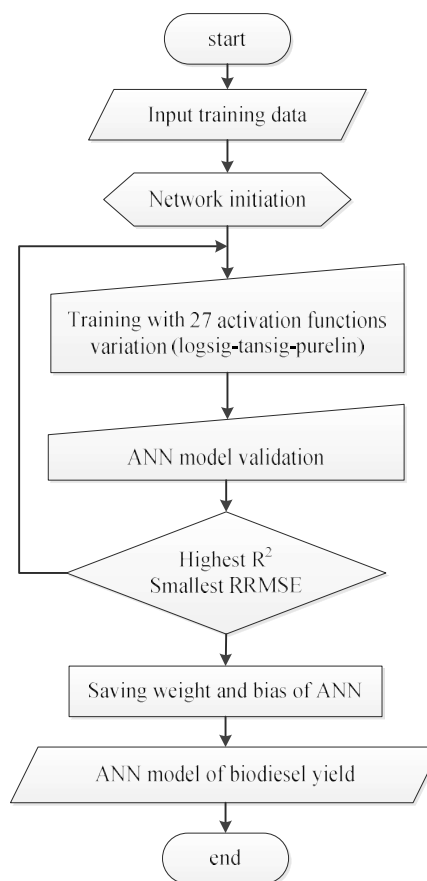

Figure 1. Flowchart fot ANN model development and validation

Figure 2 presents a form of ANN model for biodiesel yield prediction based on molar ratio, reaction temperature, and reaction time. The model consisted of three layers, namely input layer, two hidden layers, and output layer. Due to complexity of involved

variables, two hidden layers are used, each with five neurons or nodes. Karsoliya (2012) guided that neuron number of hidden layer is less than twice of the number of neurons in input layer.

The ANN model works in three steps, namely feed forward, back-propagation, and weight adjustments which are calculated based on the established equations (Widodo et al., 2013). At the first step, each input node receives an input value, x_i ($i = 1, 2, 3, \dots, n$) and forwards the signal to all nodes in the hidden layer. Each hidden layer node will add all the weighted input signals (z_in_j), which is x_i multiplied by the weight (v_{ij}) and added by received bias, b_j ($j = 1, 2, 3, \dots, p$) as in Equation 2. By activation function as in Equation 3, the signal coming out from the hidden layer node is then calculated.

$$z_in_j = b_j + \sum_{i=1}^n x_i v_{ij} \tag{2}$$

$$z_j = f(z_in_j) \tag{3}$$

In this work, three activation functions (logsig, tansig, and purelin) were selected that 27 combinations need to be validated. These three functions are defined and presented graphically in Figure 3.

Each output layer node, y_k ($k = 1, 2, 3, \dots, m$), will add up all signals from the hidden layer nodes (multiplied by weight, w_{jk} and added bias, b_k) as in Equation 4. The signal coming out of the output node is calculated by using activation function (Equation 5).

$$y_in_k = b_k + \sum_{j=1}^p z_j w_{jk} \tag{4}$$

$$y_k = f(y_in_k) \tag{5}$$

Figure 2. Form of ANN model consisting of three layers for biodiesel yield prediction

Figure 3. Definition and graphical representation of logsig, tansig, and purelin

The second step (back-propagation) starts by calculating the error information (δ_k) between each output node (y_k) with target value (t_k) associated with data for learning as in Equation 6. In order to correct the weight and bias values, correction for weight (Δw_{jk}) and bias (Δb_k) are calculated using the predetermined learning rate (α) as given in Equation 7 and Equation 8.

$$\delta_k = (t_k - y_k) f'(y_{in_k}) \quad (6)$$

$$\Delta w_{jk} = \alpha \delta_k z_j \quad (7)$$

$$\Delta b_k = \alpha \delta_k \quad (8)$$

The third step (weight adjustment) starts by calculating the error information (δ_j) between each hidden layer node (z_j , $j = 1, 2, 3, \dots, p$) with the nodes in the input layer as in Eq. 9. Then calculate the correction weight (Δv_{ij}) and correction of bias (Δb_j) to correct the weight value (v_{ij}) and bias value (b_j) as in Equations 10 and 11 using learning rate (α).

$$\delta_j = \left(\sum_{k=1}^m \delta_k w_{jk} \right) f'(z_{in_j}) \quad (9)$$

$$\Delta v_{ij} = \alpha \delta_j x_i \quad (10)$$

$$\Delta b_j = \alpha \delta_j \quad (11)$$

Each output unit is fixed by new value of its weight and bias as in Equations 12 and 13, and similarly, for each hidden unit as in Equation 14 and 15 (Widodo et al., 2013).

$$w_{jk} \text{ (new)} = w_{jk} \text{ (old)} + \Delta w_{jk} \quad (12)$$

$$b_k \text{ (new)} = b_k \text{ (old)} + \Delta b_k \quad (13)$$

$$v_{ij} \text{ (new)} = v_{ij} \text{ (old)} + \Delta v_{ij} \quad (14)$$

$$b_j \text{ (new)} = b_j \text{ (old)} + \Delta b_j \quad (15)$$

The ANN model construction was build using toolbox of MATLAB.

2.3. Model training

The ANN training process is preceded by network initialization to determine initial network architecture so that the network training process can be carried out. Twenty seven variations in activation function are combination of logsig, tansig, and purelin (Dorofki et al., 2012). Input data involved molar ratio, reaction time, and reaction temperature; whereas biodiesel yield was target parameter. Out of 144 data set (Table 1), 126 data pairs (87.5%) were used for the training using Levenberg-Marquardt training type (Anandhi et al., 2012) with learning rate (α) of 0.001 (Amini, 2008). The maximum number of iterations was set at 1000 and the smallest mean square error (MSE) is 0.00001 (Kusuma & Abadi, 2011).

2.4. Model validation

Model validation was performed to assess the accuracy between predicted and observed values. All data values (Table 1) collected at reaction time of eight minutes (12.5%) were used for validation session. In this case, validation was evaluated using relative root mean square error (RRMSE) and coefficient of determination (R^2) with a target to obtain the smallest RRMSE and the highest R^2 values.

$$RRMSE = \frac{\sqrt{\frac{1}{n} \sum_{i=1}^n (O_i - P_i)^2}}{\bar{O}} \times 100 \quad (16)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n (O_i - P_i)^2}{\sum_{i=1}^n (O_i - \bar{O})^2} \quad (17)$$

where n is the number of data, O_i is the observed value of i^{th} , P_i is the predicted value of i^{th} , and \bar{O} is the average observed value. The predicted yield is classified as ex-

cellent with $RRMSE < 10\%$, good (10-20%), fair (20-30%), and poor ($> 30\%$) (Li *et al.*, 2013).

The R^2 is used to assess the closeness of calculated values to the measurement data. The predictions are considered excellent if R^2 close to one (Despotovic *et al.*, 2016).

3. RESULTS AND DISCUSSION

3.1. ANN model for yield prediction

Table 2 shows a summary of the results from training and validation of 27 models of architectural combination of logsig-tansig-purelin activation functions. Model accuracy was evaluated from the $RRMSE$ and R^2 values of the models. We observed that during training session 24 out of 27 combination models demonstrated excellent accuracy with $RRMSE$ values of less than 10% (between 3.32 and 6.90%) and R^2 of more than 0.90 (between 0.9364 and 0.9860). The remaining three models (purelin-purelin-

purelin, purelin-purelin-tansig, and purelin-purelin-logsig) can still be grouped as good models with $RRMSE$ values between 11 and 12.5%; and R^2 values between 0.7589 and 0.8307. During the training session, the best architecture is tansig-tansig-purelin with $RRMSE$ value of 3.32% and R^2 of 0.9860. However, this model failed as the best model during validation session. The $RRMSE$ value of this model rised to 4.53%, and its R^2 decreased significantly to 0.8382.

During the validation session, 25 out of the 27 models met the excelent criteria with $RRMSE$ values of less than 10%. Two models fallen into

fair group with *RRMSE* values of 23.71 and 27.95%. Even three lowest models previously mentioned (which have *RRMSE* values of greater than 10% in the training session) and exhibited excellent *RRMSE* (< 10%) during validation. However, if the models are examined from its determination coefficients, some of the best models have very low R^2 values, and five models have even negative R^2 . This means that the accuracy of the results during the training session does not always reflect that the validation results will also be accurate. The mentioned three lowest models in the training session even displayed the worst performance with a negative R^2 values during validation session. Nine architectural models defended

themselves as excellent models with R^2 values greater than 0.90 and *RRMSE* values less than 10%. During validation session, however, the *RRMSE* of these models are lower as compared to those values during training session.

Based on the discussion above, the selection of the best activation function network architecture (that in turn will be used as a prediction model) must be based on both the smallest *RRMSE* value and the highest R^2 value in the validation session. A low *RRMSE* value indicates a small deviation from all data so that the prediction model successfully achieves a high level of accuracy. On the other side, high R^2 value indicates a very close relationship between calculated and observed biodiesel yields.

Table 2. Result from training and validation of ANN models

Activation function	Training		Validation	
	<i>RRMSE</i> (%)	R^2	<i>RRMSE</i> (%)	R^2
logsig-logsig-logsig	4.22	0.9772	5.15	0.8049

purelin-tansig-logsig	6.90	0.9364	3.51	0.9074
purelin-tansig-tansig	6.12	0.9512	3.29	0.8535
purelin-purelin-purelin	12.51	0.7589	5.98	-1.2950
purelin-purelin-tansig	10.99	0.8307	8.50	-34.7200
purelin-purelin-logsig	11.51	0.8104	8.14	-15.0800
purelin-tansig-purelin	6.40	0.9460	5.89	0.7532
purelin-logsig-purelin	6.47	0.9448	2.68	0.9042
logsig-purelin-purelin	6.89	0.9369	2.91	0.9002
tansig-purelin-purelin	6.71	0.9403	7.10	0.4931

Among the excellent models appeared during validation session, ANN models with activation function architecture of logsig-purelin-logsig, and purelin-logsig-tansig be the best two with *RRMSE* of 2.41% and 2.44%, respectively, and R^2 of 0.9355 and 0.9391, respectively. During the training

session these models (logsig-purelin-logsig and purelin-logsig-tansig) are also among the excelent models with *RRMSE* less than 10% and R^2 greater than 0.90. **Figures 4 and 5** show the scater between predicted and observed values of biodiesel yield, both in training session and validation session.

Figure 4. Scatter diagram of observation vs. prediction yield from ANN model with architecture of logsig-purelin-logsig: training result (left) and validation result (right)

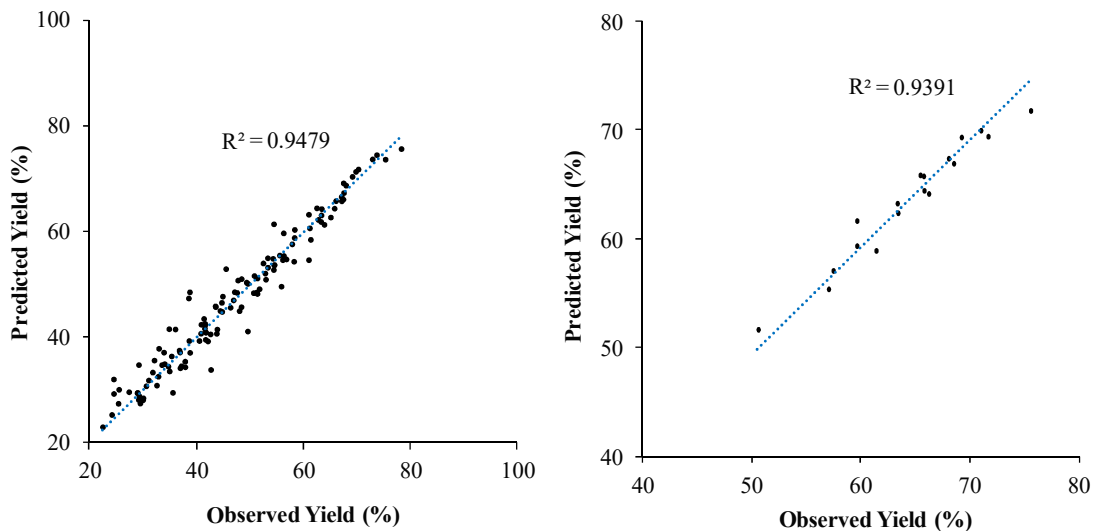

Figure 5. Scatter diagram of observation vs. prediction yield from ANN model with architecture of purelin-logsig-tansig: training result (left) and validation result (right)

Previously, we have reported the prediction of biodiesel yield at the same conditions using first order kinetic approach, and the result showed excellent predictions with *RRMSE* of 3.39%, but R^2 value of 0.8454 (Haryanto et al., 2019). Compared to the results from this study, it is clear that application of ANN model provide better prediction than those of first order kinetic. Other works also reported the superiority of the ANN model for biodiesel prediction compared to other common tools such as linear regression and partial least squares regression (Ozgun & Tosun, 2017; Balabin et al., 2011). For a comparison, **Table 3** summarized other studies on the application of ANN in predicting biodiesel content and biodiesel properties. It can be summarized that our result is comparable with other works and further emphasize that ANN model is a powerfull tool to predict biodiesel yield from different reaction conditions.

4. CONCLUSION

The network architecture of the ANN model consists of three layers with three nodes in the input layer, five nodes in the first and the second hidden layers, and one node in the output layer. The type of training used is the Levenberg-Marquardt with a learning rate of 0.001. Twenty seven (27) architectural combinations of three activation function (logsig, tansig, purelin) have been trained using 126 data set (87.5%) of biodiesel yield observed at three different molar ratios, six different temperatures and seven points reaction time, and have been validated using 18 data set (12.5%) observed at reaction time of eight minutes. Results confirmed that models with activation function of logsig-purelin-logsig and purelin-logsig-tansig be the best with *RRMSE* of 2.41 and 2.44% with R^2 of 0.9355 and 0.9391%, respectively.

Table 3. Comparison of ANN application for biodiesel-related research

Feedstock	Input variables	Output target	ANN model architecture*	Model performance**	Reference
WFO	MR, T, t	Biodiesel yield	(3:5:5:1)	$R^2 = 0.94$; RRMSA = 2.41%	This works
Oil (unspecific)	MR, T, t, P	Biodiesel yield with Super-critical Methanol	(4:17:1)	$R^2 = 0.9980$; MSE = 4.49×10^{-4}	Farobie et al., 2015
Refined palm oil	MR, T, t , catalyst	FAME content	(4:3:3:1)	$R^2 = 0.9958$; RMSE = 0.0313	Thoi et al., 2018
Cotton oil	T , blend ratio	Viscosity	(2:3:1)	MAPE = 0.19%	Ozgun & Tosun, 2017
Cotton oil	T , blend ratio	Density	(2:4:1)	MAPE = 0.02%	Ozgun & Tosun, 2017
Refined canola oil	Fatty acid composition	Cloud point	(9:6:3)	$R^2 = 0.98$; SE = 1.7	Al-Shanableh et al., 2016
Refined canola oil	Fatty acid composition	Pour point	(9:6:3)	$R^2 = 0.94$; SE = 2.1	Al-Shanableh et al., 2016
Different oils	Chemical composition	Cetane number	(5:2:4)	$R^2 = 0.9349$; MAE = 0.955	Giwa et al., 2015
Some oil types	Fatty acid composition	Flash point	(5:2:4)	$R^2 = 0.981$; MAE = 1.705°C	Giwa et al., 2015

*) First figure is the neuron number of input layer, last figure is the number of output, and figure(s) in the middle is the neuron number of hidden layer (one or more hidden layers).

**) MAE = Mean Absolute Error; MAPE = Mean Absolute Percentage Error; RMSE = Root Mean Squared Error; SE = standard Error.

5. ACKNOWLEDGEMENTS

The research was financially supported by the DGHE (Directorate General of Higher Education), the Ministry of Research, Technology and Higher Education, through research scheme of FUNDAMENTAL with contract: 071/SP2H/LT/DRPM/IV/2017585 (June 2, 2017). The views

expressed in this paper, however, are solely of the authors.

6. AUTHORS' NOTE

The authors declare that there is no conflict of interest regarding the publication of this article. Authors confirmed that the data and the paper are free of plagiarism.
