<b>Scope</b>	Today, AIP Conference Proceedings contain over 100,000 articles published in 1700+ proceedings and is growing by 100 volumes every year. This substantial body of scientific literature is testament to our 40-year history as a world-class publishing partner, recognized internationally and trusted by conference organizers worldwide. Whether you are planning a small specialist workshop or organizing the largest international conference, contact us, or read these testimonials, to find out why so many organizers publish with AIP Conference Proceedings.

## PREFACE: The 3<sup>rd</sup> International Symposium on Applied Chemistry (ISAC) 2017

This proceedings volume contains the written versions of most of the contributions presented during the 3<sup>rd</sup> International Symposium on Applied Chemistry (ISAC) 2017, which was organized in Balai Kartini Exhibition and Convention Center, Jakarta, Indonesia on October, 23-24, 2017.

ISAC 2017, as the part of Indonesian Sciences Expo 2017, carried a theme "Advances in Sustainable Energy and Chemical Feedstocks". This event was the 3<sup>rd</sup> international scientific conference organized annually by Research Center for Chemistry, Indonesian Institute of Sciences (LIPI) and Himpunan Kimia Indonesia (HKI, Indonesian Chemical Association).

The symposium was focused on bringing together the scientists and researchers working in the area of applied chemistry to present their work and to discuss the latest trends in technology developments. There were 7 keynote speakers, 48 oral presentations, and 43 poster presentations. Various aspects of chemical related topics were discussed and the presentations were divided into following topics:

- Advanced Materials and Catalysts
- Sustainable Energy
- Food, Natural Products and Pharmaceutical Chemistry
- Environmental Chemistry

We would like to thank all keynote speakers and participants for their contributions to the symposium program and for their contribution for this proceedings volume. We also deeply appreciate all the reviewers who helped to maintain the high publication quality of this volume. We also would like to thank all technical committee for their help and contributions in preparing this proceedings volume.

We are looking forward to the 4<sup>th</sup> International Symposium on Applied Chemistry that will be held next year. We hope that the symposium will be an excellent platform for all participants and committee to exchange new ideas and application experiences and to find global partners for future collaboration.

**Abstract.** Nickel and cobalt metal able to process from low grade laterite using solvent extraction and electrowinning. One of electrowinning methods which has good performance to produce pure metal is electrometal-electrowinning (EMEW). In this work, solvent extraction was used to separate nickel and cobalt which use Cyanex-Versatic Acid in toluene as an organic phase. An aqueous phase of extraction was processed using EMEW in order to deposit the nickel metal in Cathode electrode. The parameters which used in this work were batch temperature, operation time, voltage, and boric acid concentration. Those parameters were studied and optimized using the design of experiment of Taguchi. The Taguchi analysis result shows that the optimum result of EMEW was at 60°C of batch temperature, 2 Voltage, 6 hours operation and 0.5 M of boric acid.

## INTRODUCTION

Low nickel laterite is difficult to process using pyrometallurgy, however it able to process using hydrometallurgy method. One of a major problem in nickel laterite processing is many impurities hence very difficult to get pure Nickel. Liquid-liquid extraction followed electrowinning was able to produce nickel metal from laterite. Liquid extraction was used to separate nickel and cobalt from leaching solution. Meanwhile, electrowinning was used to produce nickel metal from nickel solution.

Electro Metal Electro Winning (EMEW) is one of electrowinning method which has good performance to produce high purity metal. EMEW process has many advantages such as :low operational cost, friendly for the environment, easy to install , design is compatible, it can be operate in large scale process, acid electrolyte can be recycle, it can produce high purity of metal and it can be operate in low concentration of metal solution [1,2,3 ].

In this work, low-grade nickel laterite was from Sulawesi Island which contains Fe, Ni and Co are 43.769%, 0.488 % and 0.120, respectively. Prior to process in EMEW, the laterite was processed in leaching and solvent extraction processes. In this work, Citric acid was used to leach laterite since is more friendly for the environment than sulphuric acid. Nickel and cobalt in leaching product were separated using liquid extraction. Vericatic acid and Cyanex in Toluene were used as an organic phase in solvent extraction process. This chemical successfully applied to separate of cobalt from nickel ore in sulfate solution [4, 5].

In this research, Taguchi optimization method was used to optimize the parameters in EMEW process. The parameters were boric acid concentration, voltage, temperature and operation time. In this work, boric acid was used as an additive to reduce the effect of hydrogen evolution reaction in an electrochemical process.

## EXPERIMENTS

In this work, laterite from south east Sulawesi were grinded and sieved to get a size of 150 mesh. The composition of laterite was tabulated in Table 1. The laterite was leach in 200 ml of 2 M citrate acid for 24 hours in magnetic stirrer. For liquid phase extraction a process, an organic solution of the Cyanex 272 and versatic acid in technical toluene were used. The solvent extraction was carried out in glass separating funnels with capacity 100 ml. The solvent extraction process contains the aqueous and organic phase. The aqueous phase contains an amount of nickel was a process in EMEW. In EMEW process, a cathode is aluminum, meanwhile, anode is graphite as shown in Fig. 1. DC power supply which connected with voltmeter and ampere meter hence able to adjust the voltage. The heater was used to adjust the temperature. The design of experiments of Taguchi was used in this work as listed in Table 2. These experiments have three parameters namely temperature, operation time, voltage and boric acid concentration. The mass of nickel electrodeposits were analyzed using XRF (Delta Premium XRF – Olympus).

## RESULT AND DISCUSSION

The results of this work were analyzed using a signal to noise (SN) ratio of larger the better of Taguchi were listed in Table 3. From the table shows that highest value of delta is the parameter of boric acid concentration, hence this parameter is the first rank of the parameter which affects the amount of nickel electrodeposits. The second and third rank is the voltage and temperature, respectively.

**TABLE 3.** Response Table for Signal to Noise Ratios Larger is better

Level	Temp. (°C)	Time (hour)	Voltage (v)	Boric acid concentration (M)
1	76.37	73.84	68.49	68.39

### The Effect Boric Acid Concentration towards the Mass of Nickel Electrodeposits

In this research, the boric acid concentration was varied from 0 to 1 M. Fig. 2 shows the effect of boric acid concentration towards the amount of nickel in the cathode. The results show that the increase of boric acid concentration will decrease the amount of nickel electrodeposits in the cathode. The increase of boric acid will increase the viscosity of electrolyte hence will decrease the mass transport in an electrode. However, boric acid is useful to decrease the disturbance of hydrogen generation in the cathode [6].

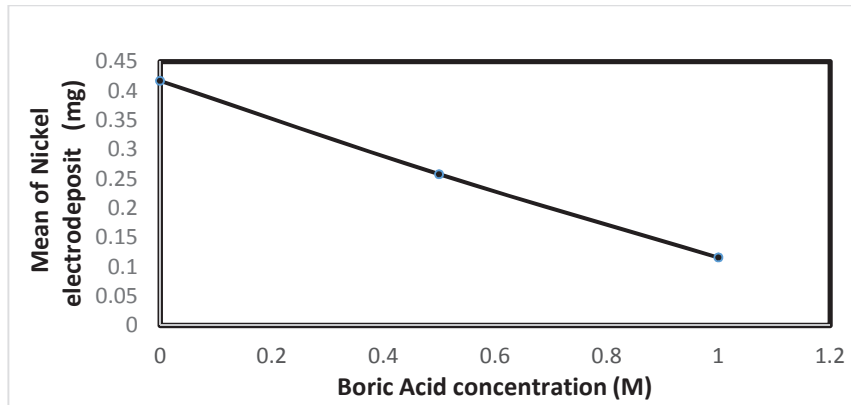

FIGURE 2. Mean effect plot for boric acid concentration towards a mass of nickel electrodeposits

### The Effect of Voltage towards the Mass of Nickel Electrodeposits

In this research, the voltages were varied from 2 to 6 volt. The effect of voltage towards nickel deposit in electrode was shown in Fig. 3. The result shows that the increase of voltage will increase the amount of nickel electrodeposits in the cathode. The increase of voltage will increase the mass transport in an electrochemical cell. However, at the certain voltage, the hydrogen evolution effect is increasing hence disturb the nickel deposited at the cathode as shown in the result of 4 volts.

FIGURE 3. Mean effect plot for voltage towards a mass of nickel electrodeposits

### The Effect of Voltage towards the Mass of Nickel Electrodeposits

Temperature was varied from 50 to 70 °C in this research. The effect of temperature towards means of nickel electrodeposits was shown in Fig. 4. The figure shows that the optimum temperature was at 60°C. The increment of temperature will increase the rate of corrosion of anode electrode [7]. This phenomenon indicates that temperature process will enhance the rate of electrowinning process [8]. The increasing of temperature also enhances the electrolyte conductivity and mass transfer [9]. However, the increment of temperature in the acidic electrolyte will enhance the hydrogen evolution which decreases the current efficiency. The increasing temperature also decreases the hydrogen overpotential, hence hydrogen evolution problem can be solved by increasing hydrogen over potential [10]. Hence, the optimum temperature is important to solve the hydrogen evolution problem.

At the temperature of 70°C the mass of nickel electrodeposits decrease as shown in Fig. 3. The increasing temperature will increase the hydrogen evolution effect. Moreover, the increment of temperature will increase the overall mass transfer include the impurities mass transfer [8]. Hence it caused the decreasing of the mass of nickel electrodeposits.

FIGURE 4. Mean effect plot for temperature towards nickel electrodeposits

### The Effect of Operation Time towards the Mass of Nickel Electrodeposits

In this work, operation times were varied from 2 until 6 hours. The effect of operation time towards the mass of nickel electrodeposits were shown in fig. 5. The figure shows that the optimum operation time is at 6 hours operation.

The enhancing of operation time increase the mass of nickel electrodeposits, since more nickel were deposited at the cathode. At the beginning of electrowinning, the mass of nickel electrodeposits were fluctuated since many impurities in electrolyte disturb the electrowinning process. There are colloid particles which have negative charge in electrolytes which were coagulated through the electrocoagulation process in EMEW reactor. These phenomena produce coagulation sludge in the EMEW reactor.

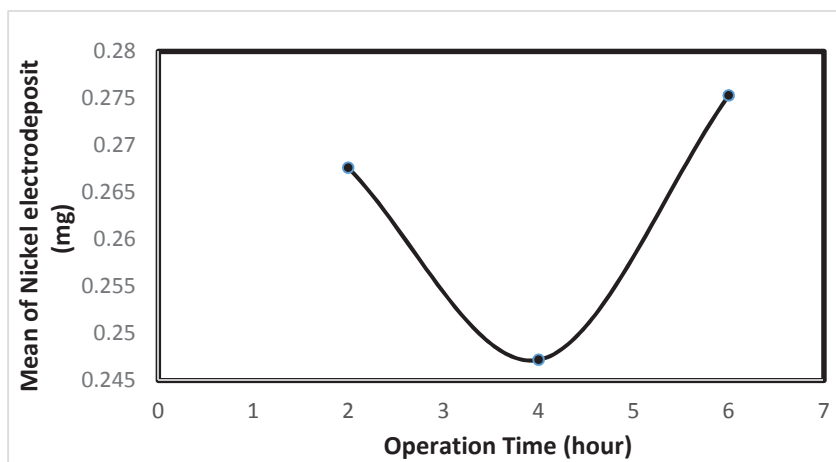

FIGURE 5. Mean effect plot for operation time towards nickel electrodeposits

### CONCLUSIONS

Electro metal electrowinning (EMEW) process from nickel laterite was conducted in laboratory scale. All parameters studied have a significant influence towards the mass of nickel electrodeposits. The optimum conditions for the EMEW process were determined using Taguchi analysis. The optimum operation conditions are at without boric acid additions, a voltage of 6 V, temperature of 60°C and operation time of 6 hours.
