SUMMARY

Organic matter or compost which applied to the soil can improve soil physical properties, such as forming microaggregates and increasing soil water holding capacity. However, the effect and the sustainability in the soil depended on the type of organic matter origin and its composition as well as its environment. This study aims to determine the fate of organic material, which is mainly its composition from cowdung using simple tools, soil dispersion ratio (DR). A soil survey was done to the area with different land use and organic matter (compost) application. The area with no compost application (0 t ha⁻¹) including in cassava, oil palm, and pineapple (3 locations), while area with banana and guava applied with compost around 50 t ha⁻¹ - 100 t ha⁻¹ and pineapple with 180 t ha⁻¹. The experiment showed that the soils were generally categorized as moderately to extremely dispersive, except cassava was little dispersive. Clay particles were mostly binded by organic material by the mechanism of cation bridge, and contributed >50% of clay aggregate form, and the highest one was in cassava.

Introduction

In humid tropical area of Lampung, Indonesia, Red acid soil are dominant, which generally have low nutrient content and soil organic carbon due to intensive leaching and rapid decomposition processes. Organic matter or compost application is mostly recommendation to improve soil fertility in the humid tropics climate.

Tisdall and Nelson (1982) pointed out that the organic binding agent could be (a) transient, mainly polysaccharides, (b), temporary, roots and fungal hyphae, and (c) persistent, resistant aromatic components associated with polyvalent metal cations, and strongly sorbed polymers.

Watanabe (2017) showed that continuous application of cattle manure could stabilize soil organic matter such as in the form of structural alterations, occlusion in soil aggregates, and adsorption to clay minerals, preserved soil organic matter derived from cattle manure.

Due to the fact that clay particle will bind carbon organic component through electrostatic binding or cation bridge ("forming pseudo sand"), a comparison between clay particles and "pseudo sand" particles could be used to evaluate the effect of organic carbon to the soil. This

concept which known as dispersion ratio was introduced by Middleton (1930). By comparing dispersed soil particles with undispersed soil particles, estimation of clay particles which was binded by organic carbon ("pseudo sand or micro aggregate") could be estimated.

This research aimed to evaluate residue of organic matter which mainly consisted of cow manure in pineapple plantation under various amount of application as well as crop rotation.

Material and Method

This research was carried out in at Terbanggi Besar, Central Lampung, Indonesia. Soil survey was done to the area with different land use and organic matter (compost) application in which the compost was 90% consisted of cow dung. The area which no compost application (0 t ha⁻¹) including cassava, oil palm, and pineapple with different age 3,6,9 months,6,9,and 15 months (harvest area), while area with banana and guava applied with compost 50 t ha⁻¹ - 100 t ha⁻¹ and one pineapple area with 180 t ha⁻¹ (code :pineapple 11). Each location was taken 4-5 soil sample with distance 25-50 m, analysed separately as replications. The compost were applied 6-8 months previous to soil sampling.

The soil dispersion ratio (DR) was defined :

$$\frac{\text{Percent silt+clay Undispersed}}{\text{Percent silt+clay dispersed}} \times 100 \% \quad (1)$$

The percentage of silt and clay in dispersed form were analysis using texture analysis with the addition of Calgon + H₂O₂ + distilled water, while only distilled water was used to get undispersed fraction. Soil texture analysis was carried out using the hydrometer method.

The classification of dispersion ratio was according to Elges (1985) which was as followed : dispersion ratios > 50% (extremely dispersive), 30%- 50% (moderately dispersive), 15% -30%(a little dispersive) and < 15% (non-dispersive).

The calculation of clay fraction that binded by organic carbon could be divided into two forms (1) binded using “glue mechanism” (2) binded by “cation brigde” mechanism”, which were calculated as follows :

Clay-gluce mechanism (Cg)

$$Cg = \text{Silt}_{\text{undispersed}} - \text{silt}_{\text{dispersed}} \quad (2)$$

Clay cation bidge mechanism (Cc)

$$Cc = \text{Sand}_{\text{undispersed}} - \text{Sand}_{\text{dispersed}} \quad (3)$$

So total partices clay that becomes “aggeregate” (Cag)

$$C_{ag} = Cg + Cc \quad (4)$$

Result and Discussions

The basic soil properties which were listed in Table 1 showed that experiments sites were dominated by clay and sand fraction which the soil texture from sandy clay to clay, with clay is dominant.

Table 1. Basic soil properties in the experiment site

Land use	Texture class*	Clay	Silt	Sand	C-organic
%					
Banana-1	SC	45.4	7.7	46.9	1.31
Banana-2	SCL	35.3	7.5	57.2	1.06
Cassava	C	53.6	7.6	38.8	1.25
Guava-1	SCL	34.0	8.5	57.5	1.34
Guava-2	SC	38.5	8.0	53.4	0.31
Oil Palm	C	49.2	10.1	40.7	0.88
Pineapple (3)	C	52.2	5.9	41.8	0.57
Pineapple (6)	C	46.1	7.5	46.4	0.57
Pineapple (9)	C	46.9	12.7	40.4	0.77
Pineapple(11)	C	50.1	6.5	43.4	1.57
Pineapple(15)	C	46.4	15.5	38.1	1.08

*C: clay; S:sandy; L : loam

The soil carbon organic were low, less than 2%, some even less than 1%, except in pineapple with 180 t/ha compost was 1.57%. With low soil carbon as well as low of kation base in Ultisol soil, the soil aggregation would be very weak

The experiment showed that the soils were generally categorized as moderately to extremely dispersive, except cassava was little dispersive (Fig.1). Although guava and banana had high compost application, the dipersion ratio failed to extremely dispersive, while pineapple with no compost only have moderately dispersive.

Fig 1. Dispersion ratio from various land use

The lowest of DR was found in cassava land use., which was usually manage with minimum tillage and management. Rasheed (2016) got that the DR value from bare soil with lowest organic matter (1.1%) was only13%. Lipiec et al. (2018) showed that the amount of readily dispersible clay was also effectec by the deformation level of the soil, which was increase in strongly compacted soil and positive correlations with bulk density.

High dispersion showed that there is binding between soil particles with the binding agency, and the binding are not strong. To see the mechanism of “glue” or “cation bridge” mechanism, the equation (2) and (3) were used to calculate from each contribution. The resultas were shown in Table 2.

Table 2 showed that clay particles were mostly binded by organic material by the mechanism of cation brigde, and contribution were above >50%, and the highest one was in cassava land use with 88% value

Table 2. Percentage of clay in silt and sand fraction

Land use	Cc	Cg	Cag	Cc/Cag	Cg/Cag
	%				
Banana(1)	22	20	41	52	48
Banana(2)	22	10	32	70	30
Cassava	44	6	50	88	12
Guava(1)	19	16	36	54	46
Guava(2)	20	12	32	63	37
Oilpalm	28	17	46	62	38
Pineapple(3)	33	16	49	67	33
Pineapple(6)	31	11	43	73	27
Pineapple(9)	29	14	43	69	31
Pineapple(11)	28	21	48	57	43
Pineapple(15)	33	12	45	74	26

However, the dispersion ratio (Fig.1) showed that the most of soils were categorized as moderately to extremely dispersive that “the bridging cation” were not enough or low to make strong aggregation between soil organic carbon and clay particles. The low cation bases in Ultisol probably the main cause that the micro aggregate built was not strong enough. Baohua and Doner (1993) stated that in the absence of polyvalent cations, negatively charged such as humic acid, may not contribute to stable soil aggregation. The effect of exchangeable cation to clay dispersion, such as Na, Fe, OC, Mg, and Al, as well as Mg, were also shown by Igwe et al. (2006). The “glue mechanism” which form “silt undispersed fraction” contribute significantly in high compost application, such as in banana, pineapple (11) and guava

Conclusion

The soil were dominately by clay fraction, however , the DR was moderately to extremely dispersive . The binding mechanism were mainly in sand fraction, using cation bridge mechanism, however, it is not strong enough due the low of soil organic carbon as well as polyvalent cation in red acid soil. The application of high compost with dominated by cowdung material only gave “glue binding mechanism” which aggregated in silt pool.
