ABSTRAK

Penelitian kelimpahan mikroalga diatom telah dilakukan di perairan Pulau Pasaran, Bandar Lampung. Penelitian ini bertujuan untuk mengidentifikasi kelimpahan mikroalga Diatom di perairan Pulau Pasaran yang dikaitkan kondisi lingkungan lainnya. Pengambilan sampel dilakukan pada bulan Mei 2017 di lima stasiun yang mewakili perairan dekat muara, area keramba jaring apung, perairan dekat pelabuhan ikan dan pelabuhan barang. Hasil penelitian ditemukan lima genus diatom yaitu: *Coscinodiscus* sp. dengan kelimpahan tertinggi, berturut-turut diikuti oleh *Nitzschia* sp., *Chaetoceros* sp., *Skeletonema* sp. dan *Thalassionema* sp.

Kata kunci: *diatom, kelimpahan, mikroalga, pulau Pasaran,*

Abstract : Epibenthic dinoflagellates are of important as primary producer in coastal and ocean

ecosystems. But it has potent toxins causing harmfull effect to marine fauna as well as to human.

The present study aimed at analyzing the abundance of three genus ; *Ostreopsis*, *Prorocentrum*

and *Gambierdiscus* in Teluk Bayur Bay, West Sumatera, which sampling were conducted in November 2014. Environmental parameters were including Nitrate, Phosphate concentration and

density of *Sargassum* vegetations were measured which presumably influence the dinoflagellates

abundance. Apparently, abundance of dinoflagellates ranged from 2061-7116 cells/g.

Sampling

stations had no effect on abundance of dinoflagellates. Water quality (N, P and *Sargassum* vegetation density) had no effect to the present and abundance of dinoflagellates, in all sampling stations.

Key words: Abundance, Benthic Dinoflagellates, *Sargassum* sp
